STEP III

CONSTRUCTING AN INSTRUMENT FOR DATA COLLECTION

This operational step includes three chapters:

- Chapter 9: Selecting a method of data collection
- Chapter 10: Collecting data using attitudinal scales
- Chapter 11: Establishing the validity and reliability of a research instrument

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

SELECTING |A| METHOD |OF| DATA |COLLECTION|

In this chapter you will learn about

- Differences in methods of data collection in quantitative, qualitative and mixed methods research
- Major approaches to information gathering
- Collecting data using primary sources
 - Observation
 - The interview
 - The questionnaire
- Methods of data collection in qualitative research
- Collecting data using secondary sources

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------

At the end of this chapter, you should have an understanding of

- The difference between primary and secondary data
- Different methods of data gathering and their respective advantages and disadvantages
- Advantages and disadvantages of open-ended and closed questions
- How to develop a questionnaire or an interview schedule
- Gathering data through qualitative, quantitative or mixed approaches

Differences in the methods of data collection in quantitative, qualitative and mixed methods research

Most methods of data collection can be used across studies that are classified as qualitative, quantitative or mixed methods. As a matter of fact the way a specific method is employed for data collection determines the classification of a study to a large extent. The distinction is mainly determined by the restrictions imposed on the philosophy underpinning the enquiry, freedom and flexibility in the structure and approach in gathering data, and the depth and freedom given to you as a researcher in probing to obtain answers to your research questions. Quantitative studies favour these restrictions, whereas qualitative ones advocate against them. The respective restrictions or flexibilities in mixed methods studies are dependent upon what and how the specific methods are employed. The classification of a method as quantitative, qualitative or mixed depends upon your answers to the following questions:

- What philosophical epistemology is underpinning your approach to research enquiry?
- How was the information collected? Was it through a structured or unstructured/flexible format of data collection or a combination of both?
- Were the questions or issues discussed during data collection predetermined or developed during data collection?
- How was the information you gathered recorded? Was it in a descriptive, narrative, categorical, quantitative form or on a scale?

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

- How was the information analysed? Was it a descriptive, categorical or numerical analysis?
- How do you propose to communicate the findings? Do you want to write in a descriptive or analytical manner?
- How many different methods were used in undertaking the study?

If your answers to the above questions are that you adopted the philosophical epistemology that is embedded in empiricism, you collected the information through an unstructured and flexible format, you identified issues for discussion during the data collection process, you recorded the information in a descriptive and narrative format and subjected it to categorical and descriptive analysis, and you communicated the findings in a non-analytical style, the research process is labelled as qualitative; otherwise it is quantitative. If you used more than one method, quantitative or qualitative or both, then it is a mixed methods study. For example, if an observation is recorded in a narrative or descriptive format, it becomes qualitative information, but if it is recorded in categorical form or on a scale, it will be classified as quantitative information, and use of both the methods would mean a mixed methods classification. Similarly for data collected through interviews. An unstructured interview, recorded in a descriptive or narrative form, becomes a qualitative method, but in a structured interview, if the information is recorded in response categories or if the categories are developed and quantified out of descriptive responses, it is a quantitative method. Descriptive responses obtained in reply to open-ended questions are all qualitative, but if the responses are numerical they will be considered quantitative. If you develop categories and quantify the categorisations as a part of the analysis of descriptive responses to an open-ended question, it becomes a quantitative analysis. Data generated by focus groups, oral histories, narratives, group interviews is always qualitative in nature; however, you can subject the data to categorical analysis which then becomes quantitative analysis. The differences between quantitative and qualitative approaches, in brief, depend upon three things: how the data was collected; how it was analysed; and how the findings were communicated.

Major approaches to information gathering

There are two major approaches to gathering information about a situation, person, problem or phenomenon. When you undertake a research study, in most situations, you need to collect the required information; however, sometimes the information required is already available and need only be extracted. Based upon these broad approaches to information gathering, data can be categorised as:

- primary data;
- secondary data.

Information gathered using the first approach is said to be collected from **primary sources**, whereas the sources used in the second approach are called **secondary sources**. Examples of primary sources include finding out first-hand the attitudes of a community towards health services, ascertaining the health needs of a community, evaluating a social programme, determining the job satisfaction of the employees of an organisation, and ascertaining the quality of service provided by a worker. On the other hand, extracting data from

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

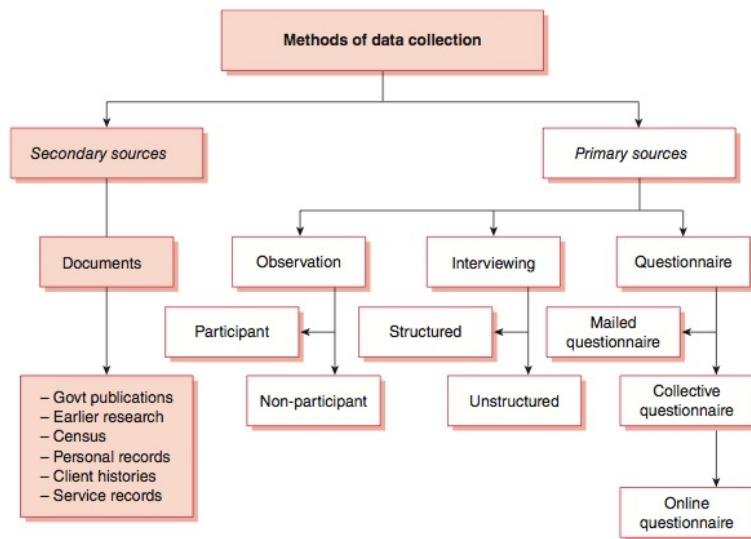

Figure 9.1 Methods of data collection

a census to obtain information on the age–sex structure of a population, the use of hospital records to find out the morbidity and mortality patterns in a community, the use of an organisation's records to ascertain its activities, and the collection of data from sources such as articles, journals, magazines, books and periodicals to obtain historical and other types of information, are all classified as information obtained from secondary sources. In summary, primary sources provide first-hand information and secondary sources provide second-hand data. Figure 9.1 shows the various methods of data collection.

None of the methods of data collection provides 100 per cent accurate and reliable information. The quality of the data gathered is dependent upon a number of other factors, which we will identify as we discuss each method. Your skill as a researcher lies in your ability to take care of the factors that could affect the quality of your data. One of the main differences between experienced and amateur researchers lies in their understanding of, and ability to control, these factors. It is therefore important for a beginner to be aware of them.

Collecting data using primary sources

Several methods can be used to collect primary data. The choice of a method depends upon the purpose of the study, the resources available and the skills of the researcher. There are times when the method most appropriate to achieve the objectives of a study cannot be used because of constraints such as a lack of resources and/or required skills.

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

In such situations you should be aware of the problems that these limitations impose on the quality of the data.

In selecting a method of data collection, the socioeconomic-demographic characteristics of the study population play an important role. You should know as much as possible about characteristics such as educational level, age structure, socioeconomic status and ethnic background. If possible, it is helpful to know the study population's interest in, and attitude towards, participation in the study. Some populations, for a number of reasons, may not feel at ease with a particular method of data collection (such as being interviewed) or comfortable with expressing opinions in a questionnaire. Furthermore, people with little education may respond differently to certain methods of data collection compared to people with more education.

Another important determinant of the quality of your data is the way the purpose and relevance of the study are explained to potential respondents. Whatever method of data collection is used, make sure that respondents clearly understand the purpose and relevance of the study. This is particularly important when you use a questionnaire to collect data, because in an interview situation you can answer a respondent's questions but in a questionnaire you will not have this opportunity.

In the following sections each method of data collection is discussed from the point of view of its applicability and suitability to a situation, and the problems and limitations associated with it.

Observation

Observation is one way to collect primary data. It is a purposeful, systematic and selective way of watching and listening to an interaction or phenomenon as it takes place. There are many situations in which observation is the most appropriate method of data collection; for example, when you want to learn about the interaction in a group, study the dietary patterns of a population, ascertain the functions performed by a worker, or study the behaviour or personality traits of an individual. It is also appropriate in situations where full and/or accurate information cannot be elicited by questioning, because respondents either are not co-operative or are unaware of the answers because it is difficult for them to detach themselves from the interaction. In summary, when you are more interested in the behaviour than in the perceptions of individuals, or when subjects are so involved in the interaction that they are unable to provide objective information about it, observation is the best approach to collecting the required information.

Types of observation

There are two types of observation:

1. participant observation;
2. non-participant observation.

Participant observation is when you, as a researcher, participate in the activities of the group being observed, in the same manner as its members, with or without their knowing

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

that they are being observed. For example, as a student of occupational therapy, you are interested in studying reactions of the general population towards people in wheelchairs. To do so, you pretend to have a handicap that requires you to use a wheelchair. As you use the wheelchair in a public area you observe the reactions of people you encounter. You make appropriate observational notes for your study when appropriate. Or suppose you want to study what it means to be prisoner and to do so, one way or another, you become a prisoner to achieve your aim. You live exactly the way other prisoners live and collect the information required to achieve the objectives of your study. Or suppose you want to study a tribe in some remote area and to do so you go and live with them and collect the data you need. Many anthropological studies have been conducted by using this approach.

Non-participant observation, on the other hand, is when you, as a researcher, do not get involved in the activities of the group but remain a passive observer, watching and listening to its activities and drawing conclusions from this. For example, you might want to study the functions carried out by nurses in a hospital. As an observer, you could watch, follow and record the activities as they are performed. After making a number of observations, you could draw conclusions about the functions nurses carry out in the hospital. Any occupational group in any setting can be observed in the same manner.

Problems with using observation as a method of data collection

The use of observation as a method of data collection may suffer from a number of problems, which is not to suggest that all or any of these necessarily prevail in every situation. But as a beginner you should be aware of these potential problems:

- When individuals or groups become aware that they are being observed, they may change their behaviour. Depending upon the situation, this change could be positive or negative – it may increase or decrease, for example, their productivity – and may occur for a number of reasons. When a change in the behaviour of persons or groups is attributed to their being observed it is known as the **Hawthorne effect**. The use of observation in such a situation may introduce distortion: what is observed may not represent their normal behaviour.
- There is always the possibility of **observer bias**. If an observer is not impartial, s/he can easily introduce bias and there is no easy way to verify the observations and the inferences drawn from them.
- The interpretations drawn from observations may vary from observer to observer.
- There is the possibility of incomplete observation and/or recording, which varies with the method of recording. An observer may watch keenly but at the expense of detailed recording. The opposite problem may occur when the observer takes detailed notes but in doing so misses some of the interaction.

Situations in which observations can be made

Observations can be made under two conditions:

1. natural;
2. controlled.

Observing a group without interfering in its normal activities, is referred to as observation under natural conditions. Introducing a stimulus to the group for it to

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

react to and observing the reaction is referred to as observation under controlled conditions.

Recording of observations

There are many ways of recording observations. The selection of a method of recording depends upon the purpose of the observation. The way an observation is recorded also determines whether it is a quantitative or qualitative study. Narrative and descriptive recording is mainly used in qualitative research, but if you are doing a quantitative study you would record an observation in categorical form or on a numerical scale. Keep in mind that each method of recording an observation has its advantages and disadvantages.

In *narrative* recording the researcher records a description of the interaction in his/her own words. Such recording clearly falls in the domain of qualitative research. Usually, the researcher makes brief notes while observing the interaction and then, soon after completing the observation, makes detailed notes in narrative form. In addition, some researchers may interpret the interaction and draw conclusions from it. The biggest advantage of narrative recording is that it provides a deeper insight into the interaction. However, a disadvantage is that an observer may be biased in his/her observation and, therefore, the interpretations and conclusions drawn from the observation may also be biased. In addition, interpretations and conclusions drawn are bound to be subjective, reflecting the researcher's perspectives. Also, if a researcher's attention is on observing, s/he might forget to record an important piece of interaction. Furthermore, in the process of recording, part of the interaction may be missed. Hence, there is always the possibility of incomplete recording and/or observation. In addition, when there are different observers the comparability of narrative recording can be a problem.

Some observers may sometimes prefer to develop a *scale* in order to rate various aspects of the interaction or phenomenon. The recording is done on a scale developed by the observer/researcher. A scale may be one-, two- or three-directional, depending upon the purpose of the observation. For example, in the scale in Figure 9.2 – designed to record the nature of the interaction within a group – there are three directions: positive, negative and neutral.

The main advantage of using scales in recording an observation is that you do not need to spend time on taking detailed notes and can thus concentrate on observation. On the other hand, one problem with using a scale is that it does not provide specific and in-depth information about the interaction. In addition, it may suffer from any of the following errors:

- Unless the observer is extremely confident of his/her ability to assess an interaction, s/he may tend to avoid the extreme positions on the scale, using mostly the central part. The error that this tendency creates is called the **error of central tendency**.
- Some observers may prefer certain sections of the scale in the same way that some teachers are strict markers and others are not. When observers have a tendency to use a particular part of the scale in recording an interaction, this phenomenon is known as the **elevation effect**.
- Another type of error that may be introduced is when the way an observer rates an individual on one aspect of the interaction influences the way s/he rates that individual on another aspect of the interaction. Again something similar to this can happen in teaching when a teacher's assessment of the performance of a student in one subject may influence his/her rating of that student's performance in another. This type of effect is known as the **halo effect**.

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

Sometimes an observer may decide to set down his/her observations using *categorical recording*. The type and number of categories depend upon the type of interaction and the observer's choice about how to classify the observation. Examples are passive/active (two categories); introvert/extrovert (two categories); always/sometimes/never (three categories); or strongly agree/agree/uncertain/disagree/strongly disagree (five categories). The use of categories to record an observation may suffer from the same problems as those associated with scales.

Observations can also be recorded using a video camera or other *electronic devices* and then analysed. The advantage of recording an interaction in this way is that the observer can see it a number of times before interpreting an interaction or drawing any conclusions from it and can also invite other professionals to view the interaction in order to arrive at more objective conclusions. However, one of the disadvantages is that some people may feel uncomfortable or may behave differently before a camera. Therefore the interaction may not be a true reflection of the situation.

The choice of a particular method for recording your observation is dependent upon the purpose of the observation, the complexity of the interaction and the type of population being observed. It is important to consider these factors before deciding upon the method for recording your observation.

The interview

Interviewing is a commonly used method of collecting information from people. There are many definitions of interviews, but it is essentially a person-to-person interaction, either face to face or otherwise, between two or more individuals with a specific purpose in mind. According to Monette et al. (1986: 156), 'an interview involves an interviewer

A study of the nature of interaction in a group

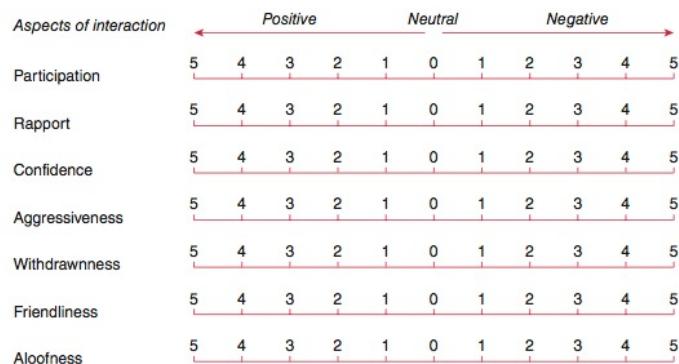

Figure 9.2 Observing/recording group interactions on a three-directional rating scale

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

reading questions to respondents and recording their answers'. According to Burns (1997: 329), 'an interview is a verbal interchange, often face to face, though the telephone may be used, in which an interviewer tries to elicit information, beliefs or opinions from another person'.

When interviewing a respondent, as a researcher, you have the freedom to decide the format and content of your questions, choose how to word them, decide how you want to ask them and in what order. The process of asking questions can be either very flexible, where you as the interviewer have the freedom to think about and formulate questions as they come to your mind around the issue being investigated, or inflexible, where you have to keep strictly to questions decided on beforehand – including their wording, sequence and the manner in which they are asked. Interviews are classified into different categories according to this degree of flexibility as in Figure 9.3.

Unstructured interviews

The main strength of an **unstructured interview** lies in having almost complete freedom in terms of its structure, contents, question wording and order. You are free to ask whatever you want, and in a format that is relevant to the situation. You also have complete freedom in terms of the wording you use and the way you explain questions to your respondents. You may formulate questions and raise issues on the spur of the moment, depending upon what occurs to you in the context of the discussion.

Unstructured interviews are extremely useful in exploring intensively and extensively and digging deeper into a situation, phenomenon, issue or problem. They provide varied and in-depth information and are best suited to identifying diversity and variety. However, their disadvantage lies in the high level of skills they require in conducting them.

Unstructured interviews are prevalent in both quantitative and qualitative research. The difference is in how information obtained through them in response to your questions

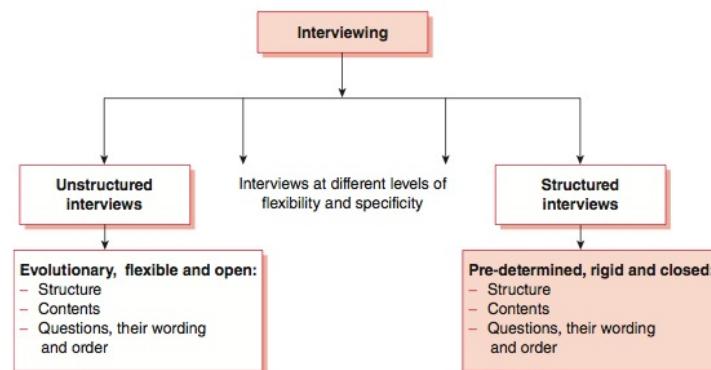

Figure 9.3 Types of interview

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

is likely to be used. In quantitative research you develop response categorisations from responses which are then coded and quantified. In qualitative research the responses are used as descriptors, often verbatim, and can be integrated with your arguments, flow of writing and sequence of logic. As unstructured interviews are predominantly used in qualitative research, they are described in greater detail under 'Methods of data collection in qualitative research' later in this chapter.

Structured interviews

In a **structured interview** the researcher asks a predetermined set of questions, using the same wording and order of questions as specified in the interview schedule. An **interview schedule** is a written list of questions, open-ended or closed, thoroughly pre-tested for standardised wording, meaning and interpretation, prepared for use by an interviewer in a person-to-person interaction (this may be face to face, by telephone or by other electronic media). Note that an interview schedule is a research tool/instrument for collecting data, whereas interviewing is a method of data collection.

One of the main advantages of the structured interview is that it provides uniform information, which assures the comparability of data. Structured interviewing requires fewer interviewing skills than does unstructured interviewing.

The questionnaire

A **questionnaire** is a written list of questions, the answers to which are recorded by respondents. Thus, respondents read the questions, interpret what is expected and then write down the answers. The only difference between an interview schedule and a questionnaire is that in the former it is the interviewer who asks the questions (and if necessary, explains them) and records the respondent's replies on an interview schedule, and in the latter the replies are recorded by the respondents themselves. This distinction is important in accounting for the respective strengths and weaknesses of the two methods and their respective use in gathering data.

In a questionnaire, as there is no one to explain the meaning of questions to respondents, it is important that the questions are clear and easy to understand. Also, the layout of a questionnaire should be such that it is easy to read and pleasant to the eyes, and the sequence of questions should be easy to follow. A questionnaire should be developed in an interactive style. This means respondents should feel as if someone is talking to them. In a questionnaire, a sensitive question or a question that respondents may feel hesitant about answering should be prefaced by an interactive statement explaining the relevance of the question. It is a good idea to use a different font for these statements to distinguish them from the actual questions. Examples in Figures 9.4 and 9.5, taken from two surveys recently carried out by the author with the help of two students, explain some of the above points.

Ways of administering a questionnaire

A questionnaire can be administered in a number of ways. Your selection of a particular method of administration depends upon the ease in assessing your respondent population

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

Where to go? A study of occupational mobility among immigrants

The questionnaire developed for this study opened with the following interactive statement:

Personal circumstances, and educational and occupational background, to a great extent determine the occupational mobility of an individual. This is especially true for immigrants. We would therefore like to ask you some questions about you and your family background. Knowledge of these factors is also important for assessing the representativeness of those who participated in the study and to understand the extent, nature and reasons of occupational mobility in relation to your background. We would appreciate your answering these questions as the information you provide will be very useful to us. We would like to emphasise that your responses are extremely valuable to us and we would greatly appreciate your answering all questions. However, if you feel that you do not want to answer a particular question, we will gladly accept your decision. We can assure you that your responses will be completely anonymous and will not be used for any other purpose.

Before asking questions about family background, the following interactive statement was inserted in the questionnaire:

Now, we would like to ask some questions about your family. Your family circumstances can affect your choice of an occupation after immigration. Again, we assure you of the complete anonymity of your responses.

Before ascertaining respondents' experiences with respect to recognition of their qualifications in Australia, the following interactive statement prepared them to be at ease with the area of enquiry:

Recognition of educational and professional qualifications, in addition to other factors, plays a major role in determining an individual's occupational mobility in a new country. In this section we would like to ask your opinion about the process of getting your qualifications recognised. We would also like to know how satisfied or dissatisfied you are with the outcome. If you are dissatisfied, we would like to know your reasons as this information may help decision makers to improve the process. Again, we assure you that your answers will be completely confidential. However, if you still feel that you do not want to answer a particular question, please feel free to omit it.

Figure 9.4 Where to go? A study of occupational mobility among immigrants

and your impressions about how they would prefer to participate in your study. The various ways in which you can administer a questionnaire are as follows:

- **The mailed questionnaire.** The most common approach to collecting information is to send the questionnaire to prospective respondents by mail. Obviously this approach presupposes that you have access to their addresses. It may not be easy to get addresses, so before you decide to collect your data through this method, make sure of the availability of addresses of your potential respondents. Usually it is a good idea to send a prepaid, self-addressed envelope with the questionnaire as this might increase the response rate. A mailed questionnaire must be accompanied by a *covering letter* (see below). One of the major problems with this method is the low response rate. In the case of an extremely low response rate, the findings have very limited applicability to the population studied.
- **Collective administration.** One of the best ways of administering a questionnaire is to obtain a captive audience such as students in a classroom, people attending a function, participants in a programme or people assembled in one place. This ensures a very high response rate as you will find few people refuse to participate in your study. Also, as you have personal contact with the study population, you can explain the purpose, relevance and importance of the study and can clarify any questions that respondents may have. The author's advice is that if you have a captive audience for your study, don't miss the opportunity – it is the quickest way of collecting data, ensures a very high response rate and saves you money on postage.

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

Ways of administering a questionnaire

Occupational redeployment: a study of occupational redeployment among state government employees

The following interactive statement was inserted in the questionnaire before asking questions about the socioeconomic-demographic background of respondents:

In order to gain an understanding of the situation of employees who have experienced occupational redeployment in state government departments during the last three years, we would like to ask some questions about your background. Your answers will help us to determine the types of occupation where redeployment has occurred and the backgrounds of the employees who have been affected by it. Please do not feel obliged to answer a question if you do not wish to, though we assure you your answers to these questions are extremely important to us to ascertain the nature and extent of the shift in your career path. We again assure you that any information you provide will be treated with strict confidentiality.

Questions about occupational history were prefaced by the following statement:

We would like to ask some questions about your work history. The answers to these questions will enable us to compare the type of work you have been doing since entering the workforce with the job you have been assigned after redeployment. This will help us to establish the nature and extent of change in your job before and after redeployment. Again, there is no obligation to answer a question if you do not want to. However, answers to these questions are extremely important to us. We assure you of the anonymity of the information you provide.

Before asking questions about the impact of redeployment, the following interactive statement was incorporated into the questionnaire:

The following questions ask you to express your opinion about different aspects of your job after and before redeployment. Your answers will help us to gauge the impact of redeployment on different aspects of your work and family situation. We would appreciate your honest opinions. Be assured that your responses will be completely anonymous.

Figure 9.5 Occupational redeployment: a study among state government employees

- **Online questionnaire.** With the advancement in communication technology, the use of the online questionnaire to collect information to answer your research questions has become quite common. You develop a questionnaire in the same way as you normally do using a program that is designed for the purpose (see Chapter 8). The main difference is that instead of personally delivering, collectively distributing or individually mailing, you post it either on a website or provide a link in your email for potential respondents to access it and respond. In the same way you could send the questionnaire to mobile phones. You can also analyse the data collected through online questionnaires using an appropriate program. There are many such programs and you need to identify the one most appropriate for your situation. Before you use this method of data collection, it is important for you to familiarise yourself with the process and program that you intend to use. In case of emailing or sending it to mobile phones you need to collect respondents' email addresses or phone numbers.
- **Administration in a public place.** Sometimes you can administer a questionnaire in a public place such as a shopping centre, health centre, hospital, school or pub. Of course this depends upon the type of study population you are looking for and where it is likely to be found. Usually the purpose of the study is explained to potential respondents as they approach and their participation in the study is requested. Apart from being slightly more time-consuming, this method has all the advantages of administering a questionnaire collectively.

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

Choosing between an interview schedule and a questionnaire

The choice between a questionnaire and an interview schedule is important and should be considered thoroughly as the strengths and weaknesses of the two methods can affect the validity of the findings. The nature of the investigation and the socioeconomic-demographic characteristics of the study population are central in this choice. The selection between an interview schedule and a questionnaire should be based upon the following criteria:

- **The nature of the investigation.** If the study is about issues that respondents may feel reluctant to discuss with an investigator, a questionnaire may be the better choice as it ensures anonymity. This may be the case with studies on drug use, sexuality, indulgence in criminal activities and personal finances. However, there are situations where better information about sensitive issues can be obtained by interviewing respondents. It depends on the type of study population and the skills of the interviewer. You need to explore and decide what would be better suited for your study and respondents.
- **The geographical distribution of the study population.** If potential respondents are scattered over a wide geographical area, you have no choice but to use a questionnaire, as interviewing in these circumstances would be extremely expensive.
- **The type of study population.** If the study population is illiterate, very young or very old, or handicapped, there may be no option but to interview respondents.

Advantages of a questionnaire

A questionnaire has the following advantages:

- **It is less expensive.** As you do not interview respondents, you save time, and human and financial resources. The use of a questionnaire, therefore, is comparatively convenient and inexpensive, especially when it is administered collectively to a study population.
- **It offers greater anonymity.** As there is no face-to-face interaction between respondents and interviewer, this method provides greater anonymity. In some situations where sensitive questions are asked it helps to increase the likelihood of obtaining accurate information.

Disadvantages of a questionnaire

Although a questionnaire has several disadvantages, it is important to note that not all data collection using this method has these disadvantages. The prevalence of a particular disadvantage depends on a number of other factors. However, you need to be aware of these disadvantages to understand their possible bearing on the quality of the data. Some of these disadvantages are as follows:

- **Limited application.** One main disadvantage is that application is limited to a study population that can read and write. It also cannot be used on a population that is very young, very old or handicapped.
- **Low response rate.** Questionnaires are notorious for their low response rates; that is, people fail to return them. If you plan to use a questionnaire, keep in mind that because not everyone will return their questionnaire, your sample size will in effect be reduced. The response rate depends upon a number of factors: the interest of the sample in the topic of the study; the layout and length of the questionnaire; the quality of the letter explaining the purpose and relevance of the study; and the

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

methodology used to deliver the questionnaire. You should consider yourself lucky to obtain a 50 per cent response rate, and sometimes it may be as low as 20 per cent. However, as mentioned, the response rate is not a problem when a questionnaire is administered in a collective situation.

- **Self-selecting bias.** Since not everyone who receives a questionnaire returns it, there is a self-selecting bias. Those who return their questionnaire may have attitudes, attributes or motivations that are different from those who do not. Hence, if the response rate is very low, the findings may not be representative of the total study population.
- **Lack of opportunity to clarify issues.** If, for any reason, respondents do not understand some questions, there is almost no opportunity for them to have the meaning clarified unless they get in touch with the researcher (which does not happen often). If different respondents interpret questions differently, this will affect the quality of the information provided.
- **No opportunity for spontaneous responses.** Mailed questionnaires are inappropriate when spontaneous responses are required, as most respondents will glance though the whole questionnaire before answering. This gives them time to reflect before answering, which may make them change their answers to some questions.
- **The response to a question may be influenced by the response to other questions.** As respondents can read all the questions before answering (which usually happens), the way they answer a particular question may be affected by their knowledge of other questions.
- **Others can influence the answers.** With mailed questionnaires respondents may consult other people before responding. In situations where an investigator wants to find out only the study population's opinions, this method may be inappropriate, though requesting respondents to express their own opinion may help.
- **A response cannot be supplemented with other information.** The information gathered by interviewing can sometimes be supplemented with information from other methods of data collection such as observation. However, a questionnaire lacks this advantage.

Advantages of the interview

- **More appropriate for complex situations.** It is the most appropriate approach for studying complex and sensitive areas as the interviewer has the opportunity to prepare a respondent before asking sensitive questions and to explain complex ones to respondents in person.
- **Useful for collecting in-depth information.** In an interview situation it is possible for an investigator to obtain in-depth information by probing. Hence, in situations where in-depth information is required, interviewing is the preferred method of data collection.
- **Information can be supplemented.** An interviewer is able to supplement information obtained from responses with those gained from observation of non-verbal reactions.
- **Questions can be explained.** It is less likely that a question will be misunderstood as the interviewer can either repeat a question or put it in a form that is understood by the respondent.
- **Has a wider application.** An interview can be used with almost any type of population: children, the handicapped, illiterate or very old.

Disadvantages of the interview

- **Time-consuming and expensive.** This is especially so when potential respondents are scattered over a wide geographical area. However, if you have a situation such as an office, a hospital or an agency where potential respondents come to obtain a service, interviewing them in that setting may be less expensive and less time-consuming.

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

- **The quality of data depends upon the quality of the interaction.** In an interview the quality of interaction between an interviewer and interviewee is likely to affect the quality of the information obtained. Also, because the interaction in each interview is unique, the quality of the responses obtained from different interviews may vary significantly.
- **The quality of data depends upon the quality of the interviewer.** In an interview situation the quality of the data generated is affected by the experience, skills and commitment of the interviewer.
- **The quality of data may vary when multiple interviewers are used.** Use of multiple interviewers may magnify the problems identified in the previous two points.
- **Possibility of researcher bias.** In an interview situation a researcher's bias either in the framing of questions and/or in the interpretation of responses obtained is always possible. If the interviews are conducted by a person or persons, paid or voluntary, other than the researcher, it is also possible that they may exhibit bias in the way they interpret responses, select response categories or choose words to summarise respondents' expressed opinions.

Contents of the covering letter

It is essential that you write a covering letter with your mailed questionnaire. In it you should very briefly:

- introduce yourself and the institution you represent;
- describe in two or three sentences the main objectives of the study;
- explain the relevance of the study;
- convey any general instructions;
- indicate that participation in the study is voluntary – if recipients do not want to respond to the questionnaire, they have the right not to;
- assure respondents of the anonymity of the information provided by them;
- provide a contact number in case they have any questions;
- give a return address for the questionnaire and a deadline for its return;
- thank them for their participation in the study.

Types of question

The way you formulate a question (open-ended or closed) and the wording you use in its framing in an interview schedule or a questionnaire are extremely important as they influence the type and quality of information you obtain from your respondents. The wording and structure of questions should therefore be clear, succinct, appropriate, relevant, and free from any of the problems discussed in the section on 'Formulating effective questions' later in this chapter. It is therefore important for you to know the types of questions commonly used in social research with their respective strengths and weaknesses. You also need to know the attributes of the wording used in their construction. This section deals with their types, characteristics, the process of formulation, and some of the common problems associated with the way they are worded.

There are two types of question commonly used in social research:

- open-ended questions; and
- closed questions.

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

In an **open-ended question** the possible response categories are *not* provided in the research instrument. In the case of a questionnaire, the respondent writes down the answers in his/her own words, but in the case of an interview schedule the investigator records the answers either verbatim or in a summary. In a **closed question** the possible answers are set out in the questionnaire or schedule and the respondent or investigator ticks the category that best describes the respondent's answer. It is usually wise to provide a category 'Other/please explain' to accommodate any response not listed. The questions in Figure 9.6 are examples of closed questions. The same questions could be asked as open-ended questions, as shown in Figure 9.7.

When deciding whether to use open-ended or closed questions to obtain information about a variable, visualise how you plan to use the information generated. This is important because the way you frame your questions determines the unit of measurement which could be used to classify the responses. The unit of measurement in turn dictates what statistical procedures can be applied to the data and the way the information can be analysed and displayed.

A. Please indicate your age by placing a tick in the appropriate category.	<input type="checkbox"/> Under 15 <input type="checkbox"/> 15–19 years <input type="checkbox"/> 20–24 years
B. How would you describe your current marital status?	<input type="checkbox"/> Married <input type="checkbox"/> Single <input type="checkbox"/> De facto <input type="checkbox"/> Divorced <input type="checkbox"/> Separated
C. What is your average annual income?	<input type="checkbox"/> Under \$10 000 <input type="checkbox"/> \$10 000–\$19 999 <input type="checkbox"/> \$20 000–\$29 999 <input type="checkbox"/> \$30 000–\$39 999 <input type="checkbox"/> \$40 000+
OR	
C(a). How would you categorise your average annual income?	<input type="checkbox"/> Above average <input type="checkbox"/> Average <input type="checkbox"/> Below average
D. What, in your opinion, are the qualities of a good administrator?	<input type="checkbox"/> Able to make decisions <input type="checkbox"/> Fast decision maker <input type="checkbox"/> Able to listen <input type="checkbox"/> Impartial <input type="checkbox"/> Skilled in interpersonal communication <input type="checkbox"/> Other, please specify

- A. What is your current age? _____ years
B. How would you describe your current marital status? _____
C. What is your average annual income? \$ _____
D. What, in your opinion, are the qualities of a good administrator?
1 _____
2 _____
3 _____
4 _____
5 _____

Figure 9.7 Examples of open-ended questions

Let us take, as an example, the question about the variable 'income'. In closed questions income can be qualitatively recorded in categories such as 'above average/average/below average', or quantitatively in categories such as 'under \$10 000/\$10 000-\$19 999/...'. Your choice of qualitative and quantitative categories affects the unit of measurement for income (qualitative uses the ordinal scale and quantitative the ratio scale of measurement), which in turn will affect the application of statistical procedures. For example, you cannot calculate the average income of a person from the responses to question C(a) in Figure 9.6; nor can you calculate the median or modal category of income. From the responses to question C, you can accurately calculate the modal category of income, but not the mean or the median income (such calculations are usually made under certain assumptions). From the responses to question C in Figure 9.7, where the income for a respondent is recorded in exact dollars, the different descriptors of income can be calculated very accurately. In addition, information on income can be displayed in any form. You can precisely calculate the mean, median or mode of income for a given study group. The same is true for any other information obtained in response to an open-ended question.

In closed questions, having developed categories, you cannot change them; therefore, you should be very certain about your categories when developing them. If you ask an open-ended question, you can develop any number of categories in any form at the time of analysis.

Advantages and disadvantages of open-ended and closed questions

Both open-ended and closed questions have their advantages and disadvantages in different situations. To some extent, their advantages and disadvantages depend upon whether they are being used in an interview or in a questionnaire and on whether they are being used to seek information about facts or opinions. As a rule, closed questions are extremely useful for eliciting factual information and open-ended questions for seeking opinions, attitudes and perceptions. The choice of open-ended or closed questions should be made according to the purpose for which a piece of information is to be used, the type of study population from which information is going to be obtained, the proposed format for communicating the findings and the socioeconomic background of the readership.

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

Open-ended questions have the following advantages and disadvantages:

- Open-ended questions provide in-depth information if used in an interview by an experienced interviewer. In a questionnaire, open-ended questions can provide a wealth of information provided respondents feel comfortable about expressing their opinions and are fluent in the language used. On the other hand, analysis of open-ended questions is more difficult. The researcher usually needs to go through another process – **content analysis** – in order to classify the data.
- In a questionnaire, open-ended questions provide respondents with the opportunity to express themselves freely, resulting in a greater variety of information. Thus respondents are not 'conditioned' by having to select answers from a list. The disadvantage of free choice is that, in a questionnaire, some respondents may not be able to express themselves, and so information can be lost.
- As open-ended questions allow respondents to express themselves freely, they virtually eliminate the possibility of investigator bias (investigator bias is introduced through the response pattern presented to respondents). On the other hand, there is a greater chance of interviewer bias in open-ended questions.

Closed questions have the following advantages and disadvantages:

- One of the main disadvantages of closed questions is that the information obtained through them lacks depth and variety.
- There is a greater possibility of investigator bias because the researcher may list only the response patterns that s/he is interested in or those that come to mind at the time of developing the research instrument. Even if the category of 'other' is offered, most people will usually select from the list of given responses, and so the findings may still reflect researcher bias.
- In a questionnaire, the given response pattern for a question could condition the thinking of respondents, and so the answers provided may not truly reflect respondents' opinions. Rather, they may reflect the extent of agreement or disagreement with the researcher's opinion or analysis of a situation.
- The ease of answering a ready-made list of responses may create a tendency among some respondents and interviewers to tick a category or categories without thinking through the issue.
- Closed questions, because they provide 'ready-made' categories within which respondents reply to the questions asked by the researcher, help to ensure that the information needed by the researcher is obtained and the responses are also easier to analyse.

Formulating effective questions

The way you ask a question, to a great extent, determines the response that you are likely to get from your respondents. Your output in terms of the responses and their quality depends upon your input in terms of questions you ask of your respondents. The wording and tone of your questions are therefore extremely important. You should be very careful about the way you formulate questions. The following are some suggestions and considerations to keep in mind when formulating questions:

- **Always use simple and everyday language.** Your respondents may not be highly educated, and even if they are they still may not know some of the 'simple' technical jargon that you are used to. Particularly in a questionnaire, take extra care to use words that your respondents will understand as you will have no opportunity to explain questions to them. A pre-test should show you what is and what is not understood by your respondents. For example:

Is anyone in your family a *dipsomaniac*? (Bailey 1978: 100)

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

In this question many respondents, even some who are well educated, will not understand 'dipsomaniac' and, hence, they either do not answer or answer the question without understanding.

- **Do not use ambiguous questions.** An **ambiguous question** is one that contains more than one meaning and that can be interpreted differently by different respondents. This will result in different answers, making it difficult, if not impossible, to draw any valid conclusions from the information. The following questions highlight the problem:

Is your work made difficult because you are expecting a baby? (Moser & Kalton 1989: 323)
Yes No

In the survey all women were asked this question. Those women who were not pregnant ticked 'No', meaning no they were not pregnant, and those who were pregnant and who ticked 'No' meant pregnancy had not made their work difficult. The question has other ambiguities as well: it does not specify the type of work and the stage of pregnancy.

Are you satisfied with your canteen? (Moser & Kalton 1989: 319)

This question is also ambiguous as it does not ask respondents to indicate the aspects of the canteen with which they may be satisfied or dissatisfied. Is it with the service, the prices, the physical facilities, the attitude of the staff or the quality of the meals? Respondents may have any one of these aspects in mind when they answer the question. Or the question should have been worded differently – for example, 'Overall, are you satisfied with your canteen?'

- **Do not ask double-barrelled questions.** A **double-barrelled question** is a question within a question. The main problem with this type of question is that one does not know which particular question a respondent has answered. Some respondents may answer both parts of the question and others may answer only one of them.

How often and how much time do you spend on each visit?

This question was asked in a survey in Western Australia to ascertain the need for child-minding services in one of the hospitals. The question has two parts: how often do you visit, and how much time is spent on each visit? In this type of question some respondents may answer the first part, whereas others may answer the second part and some may answer both parts. Incidentally, this question is also ambiguous in that it does not specify 'how often' in terms of a period of time. Is it in a week, a fortnight, a month or a year?

Does your department have a special recruitment policy for racial minorities and women? (Bailey 1978: 97)

This question is double-barrelled in that it asks respondents to indicate whether their office has a special recruitment policy for two population groups: racial minorities and women. A 'yes' response does not necessarily mean that the office has a special recruitment policy for both groups.

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

- **Do not ask leading questions.** A **leading question** is one which, by its contents, structure or wording, leads a respondent to answer in a certain direction. Such questions are judgemental and lead respondents to answer either positively or negatively.

Unemployment is increasing, isn't it?

Smoking is bad, isn't it?

The first problem is that these are not questions but statements. Because the statements suggest that 'unemployment is increasing' and 'smoking is bad', respondents may feel that to disagree with them is to be in the wrong, especially if they feel that the researcher is an authority and that if s/he is saying that 'unemployment is increasing' or 'smoking is bad', it must be so. The feeling that there is a 'right' answer can 'force' people to respond in a way that is contrary to their true position.

- **Do not ask questions that are based on presumptions.** In such questions the researcher assumes that respondents fit into a particular category and seeks information based upon that assumption.

How many cigarettes do you smoke in a day? (Moser & Kalton 1989: 325)

What contraceptives do you use?

Both these questions were asked without ascertaining whether or not respondents were smokers or sexually active. In situations like this it is important to ascertain first whether or not a respondent fits into the category about which you are enquiring.

Constructing a research instrument in quantitative research

The construction of a research instrument or tool is an extremely important aspect of a research project because anything you say by way of findings or conclusions is based upon the type of information you collect, and the data you collect is entirely dependent upon the questions that you ask of your respondents. The famous saying about computers – 'garbage in, garbage out' – is also applicable to data collection. The research tool provides the input to a study and therefore the quality and validity of the output, the findings, are solely dependent upon it.

In spite of its immense importance, to the author's knowledge, no specific guidelines for beginners on how to construct a research tool exist. Students are left to learn for themselves under the guidance of their research supervisor. The guidelines suggested below outline a broad approach, especially for beginners. The underlying principle is to ensure the validity of your instrument by making sure that *the questions you ask of your respondents directly relate to the objectives of your study*. Therefore, clearly stated objectives, research questions and hypotheses play an extremely important role in ensuring the validity of your research instrument as, in the suggested approach, each question in the instrument stems from them. It is suggested that a beginner should adopt the following approach in the development of a research instrument:

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

- Step I If you have not already done so, clearly define and individually list all the specific objectives, research questions or hypotheses, if any, to be tested.
- Step II For each objective, research question or hypothesis, list all the associated questions that you want to answer through your study.
- Step III Take each question that you identified in Step II and list the information required to answer it.
- Step IV Formulate question(s) that you want to ask of your respondents to obtain the required information.

In the above process you may find that the same piece of information is required for a number of questions. In such a situation the question should be asked once only. To understand this process, study Table 9.1 for which we have already developed a set of objectives in Figure 4.4 in Chapter 4. Note that each research objective, question or hypothesis is linked to some of the questions that you ask of your respondents. In other words, each question that you ask of your respondents can be linked to one of the objectives, research questions or hypotheses, thus enhancing the validity of your research instrument. Most of the time you might need to ask more than one question to fully achieve the total intentions of an objective or research questions.

Asking personal and sensitive questions

In the social sciences, sometimes one needs to ask questions that are of a personal nature. Some respondents may find this offensive. It is important to be aware of this as it may affect the quality of information or even result in an interview being terminated or questionnaires not being returned. Researchers have used a number of approaches to deal with this problem, but it is difficult to say which approach is best. According to Bradburn and Sudman (1979: 12–13), 'no data collection method is superior to other methods for all types of threatening questions. If one accepts the results at face value, each of the data gathering methods is best under certain conditions.'

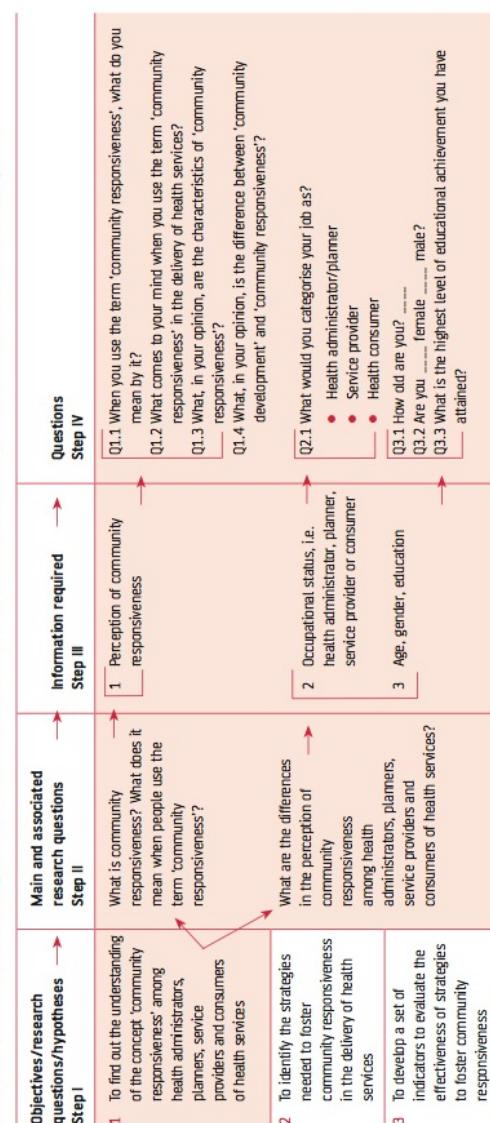

In terms of the best technique for asking **sensitive** or threatening questions, there appear to be two opposite opinions, based on the manner in which the question is asked: direct or indirect. The advantage of the direct approach is that one can be sure that an affirmative answer is accurate. Those who advocate the indirect approach believe that direct questioning is likely to offend respondents and hence they are unlikely to answer even non-sensitive questions. Some ways of asking personal questions in an indirect manner are as follows:

- by showing drawings or cartoons;
- by asking the respondent to complete a sentence;
- by asking the respondent to sort cards containing statements;
- by using random devices.

A detailed description of these methods is beyond the scope of this book.

The order of questions

The order of questions in a questionnaire or in an interview schedule is important as it affects the quality of information, and the interest and even willingness of a respondent to participate in a study. Again, there are two categories of opinion as to the best way to order questions. The first is that questions should be asked in a random order, and the second is that they should follow a logical progression based upon the objectives of the study. The author believes that the latter procedure is better as it gradually leads respondents into the themes of the study, starting with simple themes and progressing to complex ones. This approach sustains the interest of respondents and gradually stimulates them to answer the questions. However, the random approach is useful in situations where the researcher wants respondents to express their agreement or disagreement with different aspects of an issue. In this case a logical listing of statements or questions may 'condition' a respondent to the opinions expressed by the researcher through the statements.

Pre-testing a research instrument

Having constructed your research instrument, whether an interview schedule or a questionnaire, it is important that you test it out before using it for actual data collection. Pre-testing a research instrument entails a critical examination of the understanding of each question by respondents. A pre-test should be carried out under actual field conditions on a group of people similar to your study population. The purpose is not to collect data but to identify problems that the potential respondents might have in understanding or interpreting a question. Your aim is to identify if there are problems in understanding the way a question has been worded, the appropriateness of the meaning it communicates, whether different respondents interpret a question differently, and to establish whether their interpretation is different from what you were trying to convey. If there are problems you need to re-examine the wording to make it clearer and unambiguous.

Prerequisites for data collection

Before you start obtaining information from potential respondents it is imperative that you make sure of their:

- **motivation to share the required information** – It is essential for respondents to be willing to share information with you. You should make every effort to motivate them by explaining clearly and in simple terms the objectives and relevance of the study, either at the time of the interview or in the covering letter accompanying the questionnaire and/or through interactive statements in the questionnaire.
- **clear understanding of the questions** – Respondents must understand what is expected of them in the questions. If respondents do not understand a question clearly, the response given may be either wrong or irrelevant, or make no sense.
- **possession of the required information** – It is a prerequisite that respondents must have the information sought. This is of particular importance when you are seeking factual or technical information. If respondents do not have the required information, they cannot provide it.

Methods of data collection in qualitative research

To draw a clear distinction between quantitative and qualitative methods of data collection is both difficult and inappropriate because of the overlap between them. The difference between them mainly lies in the manner in which a method is applied in an actual data collection situation. Use of these methods in quantitative research demands standardisation of questions to be asked of the respondents, a rigid adherence to their structure and order, an adoption of a process that is tested and predetermined, and making sure of the validity and reliability of the process as well as the questions. However, the methods of data collection in qualitative research follow a convention which is almost opposite to quantitative research. The wording, order and format of these questions are neither predetermined nor standardised. Qualitative methods are characterised by flexibility and freedom in terms of structure and order on the part of the researcher.

As mentioned in the previous chapter, most qualitative study designs are method based: that is, the method of data collection seems to determine the design. In some situations it becomes difficult to separate a study design from the method of data collection. For example, in-depth interviewing, narratives and oral history are both designs and methods of data collection. This may confuse some, but in this chapter they are detailed as methods and not designs.

The various methods of data collection in qualitative research can be classified into three categories. These are:

1. unstructured interviews;
2. observations; and
3. secondary sources.

Unstructured interviews

Unstructured interviewing is a very common method of data collection in qualitative research. Unstructured interviews are based upon most of the characteristics that underpin the philosophy of qualitative research. They are flexible in structure, in-depth in their search, free from rigid boundaries, and at liberty to deviate from their predetermined course if need be. In addition, they differ from structured interviews in the manner the raw data is generated and analysed and the style in which the findings are communicated.

Flexibility, freedom and spontaneity in content and structure underpin an interaction in all types of unstructured interview. This interaction can be at a one-to-one (researcher and respondent) or a group (researcher and a group of respondents) level. There are several types of unstructured interview that are prevalent in qualitative research: *in-depth interviewing, focus group interviewing, narratives and oral histories*. Below is a brief description of each of these. For a detailed understanding readers should consult the relevant references listed in the Bibliography.

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

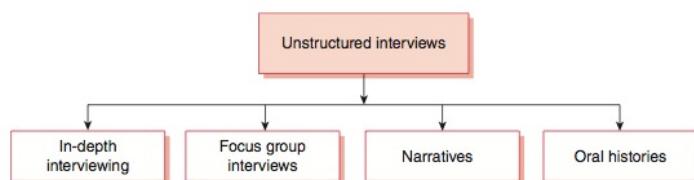

Figure 9.8 Types of unstructured interviews

In-depth interviews

The theoretical roots of **in-depth interviewing** are in what is known as the interpretive tradition. According to Taylor and Bogdan (1998: 77), in-depth interviewing is 'repeated face-to-face encounters between the researcher and informants directed towards understanding informants' perspectives on their lives, experiences, or situations as expressed in their own words'. This definition underlines two essential characteristics of in-depth interviewing: it involves face-to-face, repeated interaction between the researcher and his/her informant(s); and it aims to understand the perspectives of the latter. Because this method involves repeated contacts and hence an extended length of time spent with an informant, it is assumed that the rapport between researcher and informant will be enhanced, and that the corresponding understanding and confidence between the two will lead to in-depth and accurate information.

In its design, the in-depth interviewing is very simple. You select individuals who you think can provide you with the best information, and make contact with them to detail different aspects of the study, to seek their informed consent to their participation, to explain their expected involvement, and to decide where and when to carry out the interviews.

Recording the details of your discussions with your respondents is extremely important. You need to decide how and when you are going to record these details, and how the recorded material is to be given to your respondent(s) for confirmation and verification.

Focus group interviews

The only difference between a focus group interview and an in-depth interview is that the former is undertaken with a group and the latter with an individual. In a focus group interview you explore the perceptions, experiences and understandings of a group of people who have some experience in common with regard to a situation or event. For example, you may explore with relevant groups such issues as domestic violence, physical disability or asylum seeking in Australia. The purpose is to find out the experiences and opinions of those who have collectively experienced an event or situation.

In focus group interviews, broad areas of discussion topics are developed beforehand, either by the researcher or by the group. These only provide a broad frame for discussions which are followed by the specific discussion points that emerge as a part of the discussion. Members of a focus group express their opinions while discussing these issues.

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

As a researcher, you need to ensure that whatever is expressed or discussed is recorded accurately. Use the method of recording that suits you best. You may audiotape discussions, employ someone else to record them or record them yourself immediately after each session. If you are taking your own notes during discussions, you need to be careful not to lose something of importance because of your involvement in discussions. You can and should take your write-up of discussions back to your focus group for correction, verification and confirmation.

Narratives

The narrative technique of gathering information has even less structure than the focus group. **Narratives** have almost no predetermined content except that the researcher seeks to hear a person's retelling of an incident or happening in his/her life. Essentially, the person tells his/ her story about an incident or situation and you, as the researcher, listen passively. Occasionally, you encourage the individual by using active listening techniques; that is, you say words such as 'uh huh', 'mmmm', 'yeah', 'right' and nod as appropriate. Basically, you let the person talk freely and without interrupting.

Narratives are a very powerful method of data collection for situations which are sensitive in nature. For example, you may want to find out about the impact of child sexual abuse on people who have gone through such an experience. As a researcher, you ask these people to narrate their experiences and how they have been affected. Narratives may have a therapeutic impact; that is, sometimes simply telling their story may help a person to feel more at ease with the event. Some therapists specialise in narrative therapy. But here, we are concerned with narratives as a method of data collection.

As with focus group interviews, you need to choose the recording system that suits you best. Having completed narrative sessions you need to write up your detailed notes and give them back to the respondent to check for accuracy.

Oral histories

Oral histories, like narratives, involve the use of both passive and active listening. Oral histories, however, are more commonly used for learning about a historical event or episode or for gaining information about a culture, custom or story that has been passed from generation to generation. Narratives are more about a person's personal experiences, whereas oral histories are about historical, social or cultural events.

Suppose you want to find out about the experiences of people who were displaced after the Second World War in Europe. Talking to some of them and eliciting their stories will become the basis of your conclusions about life experiences after the War. Or suppose you want to find out about the living conditions of Aboriginal and Torres Strait Island people in the 1960s. To do so you would talk to persons who were alive during that period and ask them about life at that time.

Data collection through unstructured interviewing is extremely useful in situations where either in-depth information is needed or little is known about the area. The flexibility allowed to the interviewer in what s/he asks of a respondent is an asset as it can elicit extremely rich information. As it provides in-depth information, this technique is used by many researchers to construct a structured research instrument. On the other

PRINTED BY: campbellhm@tut.ac.za. Printing is for personal, private use only. No part of this book may be reproduced or transmitted without publisher's prior permission. Violators will be prosecuted.

hand, since an unstructured interview does not list specific questions to be asked of respondents, the comparability of questions asked and responses obtained may become a problem. As the researcher gains experience during the interviews, the questions asked of respondents change; hence, the type of information obtained from those who are interviewed at the beginning may be markedly different from that obtained from those interviewed towards the end. Also, this freedom can introduce investigator bias into the study. Using an interview guide as a means of data collection requires much more skill on the part of the researcher than does using a structured interview.

Observation

Observation is another method used for data collection in qualitative research. The difference between the use of observation in quantitative and qualitative research lies in the degree of flexibility and freedom in what and how to observe, and in recording and analysing the data generated through it. In qualitative research you have almost no framework for observation, and the recording is done in descriptive and narrative form. Use of observation in quantitative studies follows a predetermined framework and the recording is either categorical or on a scale. You can have both types of observation, participant and non-participant, as a method of data collection in qualitative research. Observation as a method of data collection has been adequately covered earlier in this chapter.

ETHNOGRAPHY

Secondary sources

There are many sources that can provide data for your qualitative research study. These sources are covered later in this chapter. The only difference in their use in quantitative and qualitative research is the way the information is extracted, analysed and communicated.

Constructing a research instrument in qualitative research

Data in qualitative research is not collected through a set of predetermined questions but by raising issues around different areas of enquiry. Hence, as such, there are no predetermined set of questions that you ask of your respondents. However, many people develop a loose list of issues and discussion points that they want to discuss with respondents or to have ready in case what they want to discuss does not surface during the discussions. This loosely developed list of issues is called an **interview guide**. It is a research tool that is used only as a back-up in qualitative designs. In the author's opinion, particularly for a beginner, it is important to develop an interview guide to ensure desired coverage of the areas of enquiry and comparability of information across respondents. Note that in-depth interviewing is both a method of data collection and a study design in qualitative research, and the interview guide is a research tool that is used to collect data in this design.

Recently the author conducted a study using in-depth interviewing and focus group methodologies to construct a conceptual service delivery model for providing child protection services through family consultation, involvement and engagement. The project was designed to develop a model that can be used by the field workers when dealing with

a family in matters relating to child protection. To start with, the author conducted a number of in-depth interviews with some staff members working at different levels and the client group to gather ideas about the issues and discussion points that they thought important to raise with the staff and clients. On the basis of these in-depth interviews, a list of likely topics/issues was prepared. This list, the interview guide, became the basis for collecting the required information from individuals and focus groups in order to construct the conceptual model. Nevertheless, the focus groups were encouraged to raise any issue relating to the service delivery. And in situations where nothing much came out of the discussions, the discussion was directed around the following topics, which formed the core of the interview guide for focus groups and in-depth interviews:

- What do you understand by the concept of family engagement and involvement when deciding about a child?
- What should be the extent and nature of the involvement?
- How can it be achieved?
- What do you think are the advantages of involving families in the decision making?
- What in your opinion are its disadvantages?
- What is your opinion about this concept?
- What can a field worker do to involve a family?
- How can the success or failure of this model be measured?
- How will this model affect current services to children?
- What additional training is needed for the staff to effectively work within the framework of the model?
- What indicators can be used to measure the effectiveness of the model?

Note that these topics only served as starting points for discussions, in the absence of issues raised by the group members. The group members were encouraged to discuss whatever they wanted to in relation to the perceived model. All one-to-one in-depth interviews and focus group discussions were recorded on audiotape and were analysed to identify major themes that emerged from these discussions.

Collecting data using secondary sources

So far we have discussed primary sources of data collection, where the required data is collected either by you or by someone else for the specific purpose you have in mind. There are occasions when your data has already been collected by someone else or already exists as a part of the routine record keeping by an organisation and what you need to do is to extract the required information for the purpose of your study. The following list gives some idea of possible secondary sources, grouped into categories:

- **Government or quasi-government publications** – There are many government and quasi-government organisations that collect data on a regular basis in a variety of areas and publish it for use by members of the public and interest groups. Some common examples are the census, vital statistics registration, labour force surveys, health reports, economic forecasts and demographic information.
